WHATS NEW IN FIREPOWER X

FirePower X brings a host of new capabilities to existing components, integration with new functionality in RAD Studio 10.4, and a new featured component in the TwwTreeView.

New TwwTreeView Component

Use the flexible new TwwTreeView component to display or edit information in a hierarchical display. The FirePower Tree is built from the ground up to be fast. Load 10000 nodes in a fraction of a second, even on mobile devices. Your nodes can be variable height. Supports checkboxes, images, and automatically uses the ‘TreeView’ style in your stylebook. You can also use this control to edit hierarchical data (such as the IDE object inspector) with the ability to embed different FirePower controls into each row.

Setting up the TwwTreeView to edit data

To setup a TwwTreeView for editing data from a table, set the following properties:

1. ColumnEdit.Visible. If you do not wish to show the editing column, set ColumnEdit.Visible to false.
2. Assign DataSource to the binding source that contains your data (such as a TBindingSourceDB). If you don’t already have one on your form, you can right-click your dataset and select Add BindSource.
3. Then to assign your treeitems to edit your data, dbl-click the component from the IDE to bring up the items editor where you can add your fields.
4. See the demo form TreeViewWalkthru that is part of our maindemo to see a complete example of using the tree to edit a record of your dataset.
5. Optional: Please note that this demo uses the CustomFormat property of the TwwTreeViewItem to automatically concatenate the strings of multiple fields to display in the tree when grouping related items together. The beauty of this is that you can see your data at design time, and do not need to create calculated fields in your dataset to compute these...
values. You should also set the ReadOnly to true so that focus does not go into this row/item. For an example, see the items in the tree captioned ‘Name’ and ‘Address’ form our demo mentioned above. Please note that you do not need to do this step if you are content with not seeing a summary of the child items data.

Adding Drag/Drop

If you wish to allow drag/drop between items on desktop platforms, then set AllowDrag to true.

Assign images to the caption column

To assign images to the caption part of the tree, assign your images property in your TwwTreeView followed by assigning the ImageName property of your TwwTreeViewItem.

Enabling multi-selection checkboxes

To enable checkboxes in the caption column, set ShowCheckboxes to true. This will enable checkboxes for all columns. To individually configure checkboxes for each item, assign the TwwTreeViewItem.CheckboxType property. To check with your code if a item is checked, then use the IsCaptionChecked property of the TwwTreeViewItem.

Configuring the type of control to edit with

To configure the control type for a tree item, use the ControlType and ControlAttributes properties of the TwwTreeViewItem.

Auto-sizing of Caption and Edit columns

Use AutoSizeColumns to configure the tree to always fully utilize available space and adjust the editing column’s width based on the width of the tree.

Common Methods

To expand or collapse the entire tree use the TwwTreeView’s ExpandAll and CollapseAll methods.

Adding tree items with code.

To add items with code use the following syntax. This will add 100 notes with 5 children in each. Make sure that you enclose your tree changes within BeginUpdate/EndUpdate or you may encounter unexpected painting issues.

```pascal
var item, childitem: TwwTreeViewItem;
i, j: integer;
begind
  wTv AS TreeView1.BeginUpdate;
  for i := 1 to 100 do
    begin
```
item:= wwTreeView1.Items.Add;
item.Text:= inttostr(i);
item.EditText:= inttostr(i);
for j:= 1 to 5 do begin
  childitem:= item.Items.Add;
  childitem.Text:= inttostr(j);
  childitem.EditText:= inttostr(j);
end
end;
wwTreeView1.EndUpdate;

**Combo Enhancements**

New enhancements in this version support customization of the drop-down icons and support for multi-selections from the dropdown list using the TwwAdvComboEdit

**Customizing the dropdown icon**

Use the ButtonImages and ButtonImageName property to override the icon used for the dropdown button.

**Enabling Multi-Selection Checkboxes**

Set ShowCheckbox to true. This will enable checkboxes in the dropdown list. To access which items are selected, you can refer to the Item’s Selected property. For instance this code shows each selection that is checked

```pascal
for i:= 0 to wwdvcomboedit1.Items.Count-1 do begin
  if wwdvcomboedit1.Items[i].selected then
    showmessage(wwadvcomboedit1.Items[i].StoredText);
end;
```

**Select predefined listbox layouts for the dropdown list**

Combos dropdown list can have multiple layouts using the new property ListboxLayoutName. You can also select this at design time by right-clicking the component and selecting *Select Item Layout*

**TwwLayoutGrid modernization**
Support rounded rectangles and spacing for items using the new `OverrideStyleSettings.Frame` property. Assign `OverrideStyleSettings.FFrame` to change the frame properties a record is presented by in the `LayoutGrid`. Normally this defaults to a simple rectangle, or just lines separating the records. By assigning these properties, you can change to a rounded rectangle and also change the colors. To enable custom framing, you minimally must set the `Frame.Enabled` to true and the `Color` property to a non-null value. You may also want to configure the frame’s `ColorOpacityPercent` and the `SelectionColor` and `SelectionColorOpacityPercent` properties. Note that when framing is enabled, the lines are no longer drawn. You can review the `mainunit.pas` file in the `maindemo` application to see an example of framing enabled.

**TwwDataGrid now supports background images**

Use the new `ImageControl` property to select a background image for the grid. You can use the `ImageControl`’s properties to have ultimate flexibility on the background image including brightness, drawing style, stretching, tiling and zooming.
